Production edition: September 2026

This guide explains every Factory application screen, the end-to-end Microsoft Agent Framework workflow, the three execution policies, both code-generation providers, and the generated assets published to Azure DevOps, GitHub, and Azure App Service.

Production application: <https://agentic-sdlc-ui-my.azurewebsites.net>

API health: <https://agentic-sdlc-api-my.azurewebsites.net/api/health>

Factory screenshots were captured from the deployed production UI at release 381828d, backed by API release 3c07f26. GitHub and published-application images are native browser captures. Azure DevOps and Azure resource images labeled **Live generated evidence** were rendered from live REST responses because unattended browser access stopped at interactive Microsoft sign-in. No synthetic work-item, test, dashboard, wiki, repository, or resource counts are used in those evidence views.

Guide scope

The guide covers:

- Authentication, guest access, access requests, and navigation.
- New Project Default Settings and every step of the Custom workflow.
- New Project Set Default Settings and every step of the Custom workflow.
- Existing and deleted projects, project details, revision, and cleanup evidence.
- Human Review, Minimal, and Autonomous execution policies.
- All 14 ordered Microsoft Foundry Prompt Agents and all ten approval gates.
- Workflow Runs, Human Approval Queue, Agent Activity, and Audit Trail.
- App Owner-only site visit totals, daily trends, unique IP addresses, approximate locations, and drill-through evidence.
- User, project access, role, agent, model, system-of-record, APIM, and configuration administration.
- Generated ADO work items, sprints, queries, dashboards, delivery plan, test plan, test run, wiki, and Azure Repo.
- Generated GitHub repository, README, pull request, and deployment workflow.
- Published Azure UI/API applications and App Service resources.
- Every in-app documentation topic.

Architecture and operating model

The Software Factory separates people, experience, orchestration, model execution, persistence, and systems of record. The Angular/Ionic UI calls a FastAPI service. Microsoft Agent Framework owns the workflow graph, durable pause/resume, and agent sequencing. Every Microsoft Foundry model call crosses Azure API Management before reaching the named Prompt Agent. Cosmos DB stores production workflow, approval, artifact, audit, project, user, notification, and checkpoint state.

Microsoft Foundry is the default code-generation provider. A project can instead select GitHub Copilot, which delegates implementation to a GitHub-hosted coding agent in the provisioned repository. That hosted execution is the documented APIM exception; Factory task state, pull-request evidence, independent code review, approvals, and audit records remain governed by this application.

The workflow is deterministic. Agents create proposals and evidence; they do not silently publish external changes. Approval policy and server-side evidence checks decide when reviewed output can update ADO, GitHub, or Azure.

Roles and access

Role	Primary responsibilities
App Owner	Full application administration, project access, permissions, configuration, audit, and deletion.
Admin	Agent, project, test, security, and operational administration according to the permission matrix.
IT User	Architecture, implementation, pull-request, release, platform, and operational decisions.
Business User	Scope, requirements, backlog, outcomes, and improvement decisions.
Guest	Read-only exploration of allowed application content.

The API is authoritative. Hiding a button in the UI does not grant or remove permission; each operation is checked again against the effective capability matrix.

Sign in

The sign-in screen supports three paths:

- Internal users on the configured tenant use Microsoft Entra ID single sign-on.
- External users use an email one-time passcode.
- Guests can continue with read-only access.

Enter an email address and select **Sign in with your email**. External users enter the six-digit code delivered by Azure Communication Services. Internal tenant users can choose **Sign in with Microsoft Entra ID**. The signed-in identity, provider, role, and effective capabilities determine visible navigation and API authorization.

Agentic SDLC — Software Factory

Orchestrate Azure AI Foundry agents across the software lifecycle — with governance from stage-by-stage review to autonomous execution.

Agentic SDLC

Foundry agents plan, design, build, test, and operate — you stay in control.

Governed access

Entra ID for staff, one-time codes for partners, guest read-only for everyone else.

Configurable governance

Choose human review at every stage, minimal checkpoints, or fully autonomous execution.

On MngEnvMCAP829495.onmicrosoft.com?

[Sign in with Microsoft Entra ID](#)

OR

👤 Continue as guest (read-only)

Guests can explore generated artifacts and reference data. They cannot create, edit, approve, or deploy.

Don't have an account?

[Request access](#)

Request access

A person without an account can open **Request access**, enter identity and business context, and submit the request for App Owner review. The form itself does not grant permissions.

Dashboard

The dashboard is the operational landing page. It summarizes project counts, pending approvals, active workflow state, and recent projects. Use it to decide whether to review a gate, inspect a running project, or create new work.

Create a project

New Project opens on **Default Settings**. This is the recommended path for most work because global connector, model, lifecycle-agent, environment, and system-of-record settings already define a governed baseline.

Default Settings

Default Settings asks only for:

- Project name.
- Optional description.
- Owner. The same value is saved as both Business Owner and IT Owner.
- Workflow execution policy: Human Review, Minimal, or Autonomous.
- Code-generation provider: Microsoft Foundry or GitHub Copilot.
- Requirements text or an attached readable requirements document.
- Optional supporting documents attached with the paperclip action.

If requirements are typed, the client creates a Markdown requirements document. If text is blank, the first readable attachment becomes the requirements source. Remaining uploads are supporting evidence. No template download is required.

FAST SETUP

Project essentials

Factory defaults handle environments, systems of record, repositories, and lifecycle agents.

Default policy

Details

Project name *

Customer Service Modernization

Description

Modernize customer service intake, routing, and operational reporting.

Owner *

business.owner@contoso.com

Workflow execution

Autonomous

Run and publish the selected workflow end to end without human approval. Evidence and audit checks still apply.

PROJECT BRIEF

Requirements

Required

Requirements

Provide guided case intake, intelligent routing, service-level tracking, and operational dashboards.

Attach files

Requirements or supporting documents - 25 MB each

Code generation

Select **Create & start workflow** only after name, owner, and requirements are present. The API provisions project systems, publishes intake documents, creates the durable workflow run, and starts eligible agents according to policy.

Custom - Step 1: Project brief

Custom exposes every project-level control in three steps. Project Brief captures name, description, separate Business and IT Owners, workflow execution policy, requirements, and supporting documents. Type requirements directly or attach a readable requirements file; architecture notes, technical constraints, mockups, images, presentations, and other evidence can be attached in the same composer. Each file is limited to 25 MB.

Workflow execution

Custom - Step 2: Delivery connections

Delivery Connections combines the repository, environment, and Systems of Record controls. Override the inherited ADO organization/project, GitHub repository and visibility, or target environment only when this project needs a different destination. ADO visibility remains restricted to the organization-supported value.

The five Systems of Record rows inherit global administration by default. Toggle **Override** only when Documentation, Work Items, Test Plans, Pipelines, or Source Code must use a different provider, URL, project, repository, or path.

Code Build / Pipelines

Inherited: GitHub Actions - https://github.com/csdmichael

Source Code Org

Inherited: GitHub - https://github.com/csdmichael

Custom - Step 3: Agents and launch

All enabled lifecycle agents are selected by default. Clear an agent only when the project intentionally excludes that responsibility. Model dropdowns inherit global policy; a project override applies to future runs and revisions. Each choice shows input and output prices per 1M tokens. Successful deployments that cannot back a Foundry Prompt Agent remain visible but disabled with the compatibility reason.

Choose the code-generation provider on this step:

- **Microsoft Foundry** runs the Code Generation Agent through APIM and publishes its approved repository proposal.
- **GitHub Copilot** creates a governed GitHub coding task, runs in GitHub's cloud, and returns the resulting pull request for independent review. Other lifecycle agents continue to use their configured Foundry models through APIM.

The compact launch summary confirms ownership, intake, destinations, environment, execution policy, Systems of Record overrides, selected agents, models, and provider before **Create & start workflow** provisions anything.

Create a project set

Project sets create two to twenty independent projects with separate workflow runs, approvals, checkpoints, artifacts, and audit records. Runs advance concurrently with a bounded worker pool.

Default Settings

The streamlined set builder applies one owner, execution policy, and code-generation provider to every project. Each project brief contains its own name, description, requirements text, and supporting attachments. Add or remove briefs before launch; at least two valid projects are required.

Custom - Step 3: Agents and launch

Shared agent, model, and code-generation-provider configuration applies across the set. A project can replace that policy without changing sibling projects. This enables one portfolio to compare models, select Microsoft Foundry or GitHub Copilot, or exclude an agent for a specific project. The final review on the same step summarizes project count, shared policy, per-project overrides, and execution modes before one submission creates an independent durable run for every project.

The 14-agent lifecycle

Every project uses the same ordered topology. The selected execution policy changes who approves a gate, not agent responsibilities, evidence requirements, connector boundaries, or audit behavior.

Order	Agent	Stage	Primary output
010	Requirements Agent	Plan	Scope, actors, functional/non-functional requirements, constraints, risks.
020	Planning Agent	Plan	Epic, Features, User Stories, Tasks, estimates, priorities, acceptance criteria.
030	Architecture Advisor Agent	Design	Architecture, data model, API contracts, threat-model and implementation decisions.
040	Code Generation Agent	Build	Application scaffold, database, tests, pipelines, branch, and pull request.
045	Code Review Agent	Build	Independent pull-request findings, remediation, test gaps, and release recommendation.
050	Test Planning Agent	Test	Test strategy, suites, cases, and requirement traceability.
060	Testing Agent	Test	Exact-commit CI assessment, defects, quality evidence, and readiness.
070	Test Automation Agent	Test	Automated runs, result evidence, and ADO test updates.
080	Security and Compliance Agent	Security	Findings, severity, mitigation, residual risk, promotion recommendation.
090	DevOps / Release Agent	Deploy	OIDC, Azure hosting, merge, deployment, smoke tests, and release record.

Order	Agent	Stage	Primary output
100	Ops Monitoring Agent	Operate	Health indicators, alerts, dashboards, incidents, and runbooks.
110	Knowledge Assistant	Operate	Cited project and operational knowledge brief.
120	Insights Agent	Improve	Metrics, thresholds, trends, risks, and prioritized improvement backlog.
130	Cost Estimator Agent	Improve	Token and cost forecast plus best-cost, best-quality, and balanced model guidance.

Approval gates

Ten gates separate estimation, generation, and publication:

1. Cost and Time Estimate Approval.
2. Plan and Scope Approval.
3. Backlog Generation Approval.
4. Architecture and Design Approval.
5. Code Generation Approval.
6. Pull Request Review Approval.
7. Test Acceptance Approval.
8. Security Review Approval.
9. Release and Deployment Approval.
10. Operate and Improve Approval.

Submission creates and attaches the preflight estimate before any model call. Human Review and Minimal require a person to approve that estimate before agents can run. Autonomous validates the artifact and records an automated approval.

A gate cannot publish until its prerequisite is approved and required artifact/tool evidence exists. Approve records the selected artifacts and triggers publication. Request Changes requires a comment and returns the owning agent output for revision. Reject closes the decision. Delegate records the replacement approver. Every transition is appended to the audit trail.

Workflow execution policies

Policy	Human checkpoints	Behavior
Human Review	All ten gates	A person reviews the estimate, every proposal, and every publication action.
Minimal	Preflight estimate plus four consequential gates	The estimate pauses before inference; routine evidence gates then advance automatically, while backlog, architecture, pull request, and release decisions pause.
Autonomous	None	Policy validates evidence and records automated decisions across the full lifecycle.

Human Review

Human Review is intended for regulated, unfamiliar, high-impact, or first-of-kind work.

The Fleet Inspection and Maintenance project shows the live full-review state. Its Overview tab identifies owners, environment, execution policy, code-generation provider, current stage, provisioned delivery systems, and lifecycle progress.

Minimal

Minimal policy pauses at the preflight estimate plus Backlog Generation, Architecture and Design, Pull Request Review, and Release and Deployment. Routine evidence gates normally advance automatically.

The Supplier Risk Dashboard project demonstrates Minimal policy with Microsoft Foundry as its code-generation provider. Its current production state is paused at Pull Request Review in the Build stage: routine code-generation, test, and security evidence advanced under policy, while the consequential pull-request decision remains a human checkpoint. Minimal reduces approval clicks, but it never bypasses guardrails, evidence checks, authorization, or audit.

The workflow distinguishes retained human checkpoints from policy-automated checkpoints on every agent row. The same proposal editing, selection, evidence, and publication controls remain available whenever Minimal requires

a person to decide.

The screenshot displays the 'Agentic SDLC — Software Factory' interface. The top navigation bar includes the user profile 'Michael Yaacoub, App Owner' and a 'Sign out' button. The left sidebar lists various operations and admin functions. The main content area is titled 'Human review' and shows a proposal for 'Code Review Agent output'. The proposal text states: 'I can provide the review format and decision framework, but I can't run an actual build-stage code review without the pull request diff or repository contents.' The proposal is currently in the 'Awaiting Approval' stage. Below the proposal, there are three sections: 'Status', 'What I need to review', and 'Reviewable proposal'. At the bottom, a 'Pull Request Review Approval' section shows a workflow with three steps: 'Review' (Select the items to publish), 'Decide' (Approve or return with comments), and 'Proceed' (Publish and unlock the next agent). The current status is 'Awaiting Approval'.

Autonomous

Autonomous policy runs the same agents and evidence checks with system-recorded gate decisions. It does not bypass guardrails, server authorization, APIM, external-system verification, or audit.

Equipment Calibration Compliance demonstrates a completed autonomous run.

4 items

Project Details workspace

Project Details is the primary project command center. Four tabs separate the current state without losing context: **Overview**, **Agent workflow**, **Generated assets**, and **Human review**. Tab badges show agent, asset, and review-attention counts. Dense model, system-of-record, run-evidence, and checkpoint-history sections remain collapsible so the current workflow state stays prominent.

Overview, models, and revision

The Overview tab shows owners, environment, execution mode, code-generation provider, current stage, provisioned ADO project and GitHub repository, visibility, and all eight lifecycle-stage states. **Agent models** expands only when a project-level override must be inspected or changed. A completed project also displays **Revise completed workflow**, which can restart from Requirements, Planning / Work Items, or Architecture while retaining published artifacts as the traceable baseline.

Provisioned systems

The Overview tab links the ADO project and GitHub repository and surfaces provisioning status, visibility, reason, and actionable failure detail.

Lifecycle and agent workflow

The Overview stage strip shows all eight lifecycle states. The Agent workflow tab then presents all 14 ordered agents; each row includes the named identity, last run, proposal state, prerequisite, checkpoint type, and current action. Knowledge Assistant and Cost Estimator are advisory and therefore show an automated, no-publication-gate checkpoint.

Project Cost and Usage

Project Cost & Usage is the detailed FinOps ledger. It summarizes project count, tokens, and estimated USD cost, then breaks each project down by model, input/cached-input/output tokens, run count, and elapsed delivery time. The model-selection matrix compares configured price and quality scores and identifies the best-cost, best-quality, and balanced choices.

Provider-reported usage is kept separate from estimated usage. GitHub-hosted Copilot code generation is identified as an externally billed, unmetered run and is not silently represented as Foundry token cost. Configured rates are planning estimates; provider billing exports remain authoritative.

Email notifications

Azure Communication Services sends lifecycle email to deduplicated Business and IT Owners. Persistent notification records make delivery idempotent across retries and API restarts. Notifications are emitted when:

- A project is created, including execution mode, environment, creator, and a link back to the Factory.
- A workflow reaches an actionable human approval gate.
- A workflow fails and requires operator attention.
- A project completes its full lifecycle.
- Project Access grants or removes managed Factory, ADO, and optional GitHub access.

The Project Access email groups Factory, Azure DevOps, and GitHub destinations into one message and copies the configured audit recipient. When GitHub username is blank, GitHub access and GitHub-specific email copy are omitted.

Description

No description was supplied at intake. This epic is the delivery container for Equipment Calibration Compliance . It groups every feature, user story, and task the Agentic SDLC workflow derived from the approved requirements and UX mockups. Scope was approved by a human reviewer at the Requirements gate before any work item was created. Anything outside that approved scope belongs in a new epic rather than this one. Business owner: myaacoub@microsoft.com. IT owner: myaacoub@microsoft.com. Target environment: Dev. Source: Planning Agent output , produced by the Planning Agent and accepted at the approval gate on 2026-08-27.

Acceptance criteria

Defined on child stories and tasks.

Sprints

Planning creates three dated two-week iterations and subscribes the default team so sprint boards, capacity, burndown, and current-iteration queries work.

Equipment Calibration Compliance

Generated by the Agentic SDLC workflow.

Generated by the Agentic SDLC / Software Factory. Every change reaches this repository through an approved human gate — no agent merges its own work.

About

Calibration due dates are tracked on a spreadsheet held by one metrology technician, so instruments drift past due without anyone noticing until an auditor asks. As-found readings are written on a certificate pad and filed, which means that when an instrument is found out of tolerance nobody can answer the only question that matters: which product

GitHub Actions deployment

The generated workflow uses OIDC, builds/tests UI and API, deploys both App Services, performs bounded health/CRUD smoke tests, and writes published links back to README.

The screenshot shows a GitHub repository page for `csdmichael/equipment-calibration-compliance`. The `Actions` tab is selected, displaying a workflow run titled `Equipment Calibration Compliance: generated application scaffold #7`. The workflow run is successful, triggered by a push to the `main` branch. The status is `Success`, and the total duration is `6m 49s`. The workflow file is `deploy-azure.yml`, which runs on push. The workflow steps show a `deploy` step that completed successfully in `6m 44s`. The annotations section shows a warning about Node.js 20 being deprecated, stating that the following actions target Node.js 20 but are being forced to run on Node.js 24: `actions/checkout@v4` and `actions/setup-node@...`. The left sidebar shows the `Summary` tab selected, with links to `All jobs`, `Run details`, `Usage`, and `Workflow file`.

Published Azure applications

The following native screenshots use the healthy Field Service Work Orders deployment because it provides populated user workflows and a matching API collection.

Published UI

The generated Angular/Ionic application exposes the domain workflow. The queue is loaded from the deployed API and contains seeded work orders.

Field service Work Orders			
WORK ORDER QUEUE	ASSET DETAIL AND DIAGNOSTICS	SERVICE LOG AND PARTS	COMPLETION AND SIGN-OFF
Sample Work Order 1 WO-0001			new
Sample Work Order 2 WO-0002			in-progress
Sample Work Order 3 WO-0003			complete
Sample Work Order 4 WO-0004			new

Selecting an item opens operational detail and enables the remaining service workflow tabs.

Field service Work Orders			
WORK ORDER QUEUE	ASSET DETAIL AND DIAGNOSTICS	SERVICE LOG AND PARTS	COMPLETION AND SIGN-OFF
Sample Work Order 1			
Reference: WO-0001			
Status: new			
Priority: low			

Published API

FastAPI Swagger documents health plus generated collection CRUD operations and schemas.

The screenshot displays the Swagger UI for the 'Field service Work Orders API'. At the top, the API title is followed by version '0.1.0' and 'OAS 3.1' in a green badge. Below this is the OpenAPI JSON file path and a description: 'REST API for Field service Work Orders. Generated by the Agentic SDLC workflow.' The interface is organized into expandable sections. The 'health' section, described as a 'Liveness probe used by the deploy pipeline.', contains a single GET endpoint at '/health' with the description 'Health'. The 'work-orders' section, described as 'Work Orders managed by this service.', lists five endpoints: a GET endpoint for listing items, a POST endpoint for creating items, and GET, PATCH, and DELETE endpoints for individual item management. Each endpoint is color-coded by method (blue for GET, green for POST/PATCH, red for DELETE). The 'Schemas' section at the bottom shows two error schemas: 'HTTPValidationError' and 'ValidationError', both of type 'object'.

Insights Agent	model-router (balanced: cost + quality) (\$2.00 input / \$12.00 output per 1M tokens)
Cost Estimator Agent	

APIM and Configuration

APIM & Configuration presents sanitized runtime configuration and connector readiness without exposing secrets. All Microsoft Foundry model execution remains behind the configured APIM gateway; GitHub-hosted Copilot generation is the explicit external-provider exception described above.

Site Visit Analytics

Site Visit Analytics is available only to the immutable App Owner role at `/admin/site-visits`. Date controls filter the complete view. Summary metrics report total visits, unique IP addresses, active days, and resolved-location coverage. Visits by day and top locations support trend analysis, while the visitor table shows first and last visit times and days visited.

Select a day or visitor address to drill through to timestamp, IP address, approximate city/state/country, referrer, and browser/device metadata for each page load. Drill results are paginated. The API does not cache owner analytics responses, and non-App Owner roles are denied even if they attempt to navigate directly to the route.

Exact IP addresses are redacted in this public guide image. Authorized App Owners see the complete values in the live application.

In-app documentation

The application includes role-accessible reference topics.

Overview

A governed software factory where 14 named Microsoft Foundry Prompt Agents produce reviewable SDLC proposals under configurable human and automated approval policies.

Microsoft Agent Framework owns sequential workflow topology and pause/resume behavior. Azure API Management is the only model execution boundary.

Agent output is saved first. Review modes let humans edit and select artifacts; autonomous mode validates evidence and records system decisions before publication.

An independent model reviews generated code before pull-request approval. A final cost estimator combines token telemetry and historical project statistics to improve future model choices.

Architecture

The solution separates experience, orchestration, model execution, persistence, and systems of record into independently governed tiers.

Tiers: Angular/Ionic UI, FastAPI service, configurable persistence (file for local dev, Cosmos DB in Azure), and a Microsoft Agent Framework orchestration tier.

Each runtime definition invokes its matching named Prompt Agent through the APIM wildcard gateway and the Foundry Responses protocol.

Configuration is separated by tier: UI config, API config, DB/persistence config, and agent config each live in their own config folder.

Agent Responsibilities describes all 14 roles, stages, human owners, checkpoints, and outputs, including provider-neutral Code Review and the final advisory Cost Estimator.

Security and guardrails

Security & Guardrails explains identity, least privilege, secret handling, pre/post model checks, correlation, and audit.

Security & guardrails

Security is enforced across identity, workflow, model access, content, integrations, and audit.

No secrets in code. Secrets come from environment variables or managed identity.

Guardrail policies run before and after agent output: content safety, PII redaction, and secret scanning. Blocking findings fail the run.

Role checks are enforced on both the UI (hidden navigation) and the API (server-side authorization).

Correlation IDs flow across UI, API, APIM, agent calls, and audit logs.

Code review uses model separation to reduce correlated generation/review failure. Project-level model settings reject a reviewer deployment that matches the generator deployment.

Cost reporting separates provider-reported usage from estimated usage and explicitly identifies unpriced or externally unmetered runs.

Configured USD rates support planning; cloud billing exports remain authoritative.

Cosmos DB stores project statistics and Agent Framework checkpoints in logical partitions. Managed identity and private networking remain the production access path.

Cost, usage, and model governance

Cost, Usage & Model Governance explains measured versus estimated tokens, persisted project statistics, external unmetered runs, comparison views, configured pricing, and how the Cost Estimator recommends future model portfolios.

Cost, usage & model governance

Every project exposes a durable FinOps view of token consumption, estimated model cost, model mix, and elapsed delivery time.

The API captures input, cached-input, output, and total tokens from Foundry Responses usage. When a provider omits usage, the record is clearly marked as estimated instead of being presented as exact.

Final project statistics are persisted after the complete 14-agent workflow finishes. They include per-model and per-agent breakdowns, total estimated USD cost, start/end timestamps, duration, pricing coverage, and external unmetered runs.

Project Cost & Usage shows the detailed ledger and model-selection matrix. Project Cost Comparison renders side-by-side bars for total cost, total tokens, and start-to-finish time.

The Cost Estimator Agent receives the current project snapshot plus recent completed-project statistics. It recommends lowest-cost, highest-quality, and balanced model portfolios while stating assumptions and billing limitations.

Update per-million-token planning rates and quality scores in the API pricing configuration whenever provider pricing or internal quality benchmarks change.

End-to-end operating flow

1. An authorized creator opens New Project or New Project Set.
2. The creator supplies scope, owners, policy, and requirements, using defaults or Custom overrides.
3. The API validates input, provisions ADO/GitHub, publishes intake files, creates the durable workflow run, and sends owner notification.
4. Requirements and Planning agents produce scope and backlog proposals.
5. Policy or a human gate publishes reviewed work items, sprints, queries, dashboards, and delivery plan to ADO.
6. Architecture produces solution, data, API, security, and implementation decisions and publishes approved documentation.
7. Code Generation either invokes its Foundry Prompt Agent through APIM or delegates to the selected GitHub Copilot cloud agent, then records the governed branch, task, and pull-request evidence.
8. Code Review independently evaluates the pull request with a model distinct from the Foundry generator, or provider-neutral review when Copilot generated the code.
9. Test Planning, Testing, and Test Automation create ADO test assets and verify exact-commit CI evidence.
10. Security and Compliance validates findings and residual risk before release.
11. DevOps / Release configures GitHub OIDC, provisions Azure App Services, verifies/merges the persisted PR, dispatches one deployment, runs smoke tests, updates README links, closes related work items, and publishes the ADO wiki.
12. Ops Monitoring, Knowledge Assistant, and Insights produce operating and improvement evidence.
13. Cost Estimator runs as the final advisory agent after Operate and Improve, combining measured usage, configured prices, and completed-project history into best-cost, best-quality, and balanced recommendations.

14. The run completes, durable cost statistics and audit remain queryable, owners receive completion notification, and a later revision can restart from an earlier stage.

Troubleshooting

- **A project is waiting:** Open Project Details and inspect the first Awaiting Approval gate, missing evidence message, or failed automation banner.
- **An agent cannot run:** Confirm its prerequisite gate, selected-agent policy, model availability, APIM path, and circuit-breaker state.
- **GitHub Copilot generation is not in Foundry token totals:** Copilot runs in GitHub's cloud and is reported as externally billed/unmetered. Check GitHub billing for that execution; the Factory still records its task, pull request, review, approvals, and audit evidence.
- **ADO or GitHub publication failed:** Open Generated Assets, Agent Runs & Artifacts, and Audit Trail for the exact connector error and correlation ID.
- **A project has no description:** New intake derives two or three sentences from readable functional requirements when the description is blank.
- **GitHub access should be skipped:** Leave GitHub username blank in Project Access. Do not enter a placeholder value.
- **Access must be removed:** Use Project Access Remove mode with the same email and selected projects. Pre-existing memberships are preserved.
- **A generated API is cold:** Warm `/health`, then reload the UI. App Service startup may take longer on a shared free/basic plan.
- **A deployment appears stale:** Verify the exact GitHub Actions run and deployed behavior; App Service may need a worker recycle after some deployment methods.
- **Native ADO capture prompts for credentials:** Use approved interactive organizational sign-in. This guide uses live REST-backed evidence panels rather than storing browser credentials.
